About variable marks

When you send jobs to an output device, you may want to include information identifying that output, such as the name of the color separation, job name, and output date. Variable marks, also known as marks or slug lines, allow this information to be gathered at the time of output. When an output process template is executed, variable marks are replaced with the correct information.
You can add variable marks to your output either using an imposition marks file or using the process template settings.
