

Create a rule set using a filter flow action

Scenario

You want to use a **Filter** flow action to determine how to refine a group of input files. Some of the input files are known and trusted and can bypass the refine process. Other input files must be refined. You want to use an RBA filter to determine which input files should be refined and which should bypass the refine process. Input file identification will be determined by the name of the input file.

Follow these procedures to complete this scenario.
